**Abstract**— *The objective of this work is to compare the results of the classical identification of diatoms by optical microscope to the automatic identification of the diatoms. For the first method, we determined the diatoms using an optical microscope and the identification keys.*

*Concerning the second method, we relied on the processing and analysis of the images to automatically recognize a diatom. Our aim is to compare the results of the manual identification of diatoms with the results of the automatic identification of the same sample. The purpose of this comparison is to verify whether the automatic analysis can give acceptable results in order to replace the manual determination. We used the Image j software for the development of our program and based on the notion of points of interest and the freeman code.*

*The results of the determination of the diatoms by optical microscope which lasted more than one month did not exceed 92% (for 104 species of diatoms 96 species were identified), whereas the automatic identification requires only a few seconds, with much better results (97%).*

**Keywords**— *Diatoms, current, identification by microscope, automatic identification, digital image processing, Fouarate, Kenitra, Morocco.*

## I. INTRODUCTION

Rich in thousands of species (Mollo and Noury, 2013), diatoms are diversified into several groups, genera and species, and have been the subject of extensive discussions and divergent opinions concerning the taxonomy and nomenclature (Tolomio, 2011). This diversification presents morphological variations making the identification of diatoms by optical microscope tedious (J. Prigiel and Coste, 1993; Chahboune *et al.*, 2015; Siddour *et al.*, 2007; Manoylov. 2014) and heavy for the uninitiated. Automatic image recognition provides a valuable help both for the identification of diatoms (Chahboune *et al.*, 2015), and

especially as a teaching tool to help in identification for new diatomists.

Our study aimed to use two identification methods of the diatoms of the Merja Fouarat, one is the classical method which is based on the identification key using the optical microscope, the other is the automatic method which relies on image analysis and interpretation techniques. The comparison of the two methods allowed us to define to what extent the automatic identification method can meet the challenges encountered in order to identify the diatoms precisely and in a very short time.

## II. MATERIALS AND METHODS

### 1- Characteristics of the study sites

Located on the plateau of Mamora, between the plio-quaternary clay plain of the Rharb and the granitic, paleozoic, western schisto-sandstone Meseta, the Merja Fouarate is the site of a water table located in the sand and limestone sand of the Plio-Villafranchien (Combe, 1975), with Mediterranean climate and pronounced oceanic influence (sub-humid low temperature, temperate in winter).

The Merja Fouarate is fed by:

- The inflows of Oued Fouarate representing the first important valley of the Mamora plateau (Thauvin, 1966) with a source located at Ras-El-Aîn, about 10 km south of the Merja;
- Abundant and close rainfalls lead to the exfiltration of natural water from the groundwater (Nassali *et al.*, 2002), accompanied by short duration floods;
- Wastewater from peripheral neighborhoods.

## 2- Sampling

At the five stations, three diatom sampling campaigns were performed. The diatoms were removed by scratching natural substrates using a nylon bristle brush. The samples thus obtained were immediately fixed in formalin (10%). After a few days of decantation, the diatoms were treated with nitric acid on a hot-plate then mounted with naphrax between the blade and the lamella.

## 3- Identification of diatoms

The identification of diatoms by optical microscope was carried out with the help of the work of Germain, 1981; Krammer and Langbertalot, 1986, 1988, 1991a and b). The optical microscopic counts of at least 450 frustules were performed on permanent preparations. The numbers of each taxon were transformed into relative abundance (Chahboune *et al.*, 2011). The automatic identification consisted of a classification from the same sample. This identification relied on the software Image j (Chahboune *et al.*, 2015), a digital image processing application developed at the National Institute of Health (Wayne, 1997).

## III. RESULTS AND DISCUSSION

The identification of the diatoms by microscope required an enormous effort both in terms of learning, which lasted five

months in order to acquire the skills of a diatomist, and in terms of the determination of the diatoms which lasted longer than a month with a result approaching 92%, for 96 diatom species out of 104. 8 species (*Navicula* sp 1, *Navicula* sp2, *Navicula* sp3, *Nitzschia* sp1, *Nitzschia* sp2, *Gomphonema* sp1, *Gomphonema* sp2, *Surerella*) were difficult to classify. Indeed, the particularities of some potentially more complex species are difficult to solve (Tolomio, 2011; Ector and DašaHlúbiková, 2010; Lavoie, 2008; Coste and Ector, 2000).

The automatic identification in turn required a pre-processing phase of the images and the results were around 97%. The automatic classification work confirms our approach:

- ADIAC teams have achieved good classification rates above 96% on a much larger sample, even surpassing the results of human experts. (Jalba *et al.*, 2004).
- The work of (Siddour *et al.*, 2007) which consisted in characterizing the contour of the diatoms according to a vector of the Fourier descriptors from a database of diatom images, obtained a good classification rate of 97%. As for (Claudon, 2007), he presented a classification method based also on the windowed Fourier transform, but taking into account the internal structures and the ornamentalations of the diatoms. His analysis on a reference sample was approaching 100%.

Therefore, we find that the automatic classification is effective. However, the automatic recognition of diatoms is a long term project because its success requires that the image database be continuously supplied. Clearly, the system we have developed can only identify the diatoms listed. If a diatom does not exist in the database, it will not be recognized. Further work should help fuel the image database.

## IV. CONCLUSION

We can infer that automation has a double contribution: it allows a rapid identification with great success results, and especially allows the novice to avoid a tedious learning.
